

(a) Local and propagated risk

(b) Amplification and convergence

Panel (a) uses the raw edge weights printed in Section 3.5. The acyclic chain is nilpotent, so $\rho(\lambda W^T) = 0$ and Eq. (10) converges for all λ ; the margin is shown for the cyclic variant, whose convergence limit is $\lambda^* = 1/\rho(W^T)$. The operating point $\lambda = 0.45$ lies well inside it.
